

**Principle 5:  
Grades 6-8**

**Principle 5:  
The ocean supports a great diversity of life and ecosystems.**

The ocean provides vast living space and unique ecosystems from the surface through the water column to the sea floor.

**Diversity of Ecosystem**

**Diversity of Life**

**A.** Ocean ecosystems vary widely, based on the variety of environmental factors and the community of organisms living there.

**B..** The diversity of ocean ecosystems allows for many unique lifeforms with many unique adaptations.

**Primary Productivity**

**A.1.** Ocean ecosystems with the greatest abundance of life occur where environmental conditions and/or adaptations allow for high levels of productivity.

**A.15.** Differences in light, temperature, pressure, density and chemical makeup of this fluid environment lead to distinct vertically and horizontally distributed ecosystems.

**A.21.** Ocean ecosystems are connected to each other via a series of food webs.

**B.1.** The diversity of phyla is greater in the ocean than on land.

**B.3.** The ocean supports a range of animals from the smallest living thing to the largest animal on Earth.

**B5..** Organisms in the ocean exhibit an amazing variety of adaptations to sound, density, pressure, patchy food distribution & other environmental factors.

**A.2.** Most primary productivity in the ocean takes place at the surface where there is plentiful sunlight for photosynthesis and nutrients to support growth.

**A.5.** Some ecosystems function independent of sunlight energy.

**A.8.** There are six places in the ocean, all on west coasts, with the right environmental conditions to create the most productive areas. These are the coastal upwelling zones.

**A.11.** Coral reefs occur where the water is warm and there are not many nutrients in the water, and yet they are very productive ecosystems.

**A.13.** Environmental conditions in estuaries (e.g., shallow, brackish water) and in mangroves (lots of decaying organisms) result in highly productive nursery areas for a great many ocean organisms.

**A.14.** At the poles, nutrients flowing into the ocean from melting glaciers, combined with long, sunny days in the summer, result in productivity and abundance unequalled anywhere else in the world.

**A.16.** Ecosystems exist in layers of habitats and microhabitats due to gradients in specific environmental factors, such as temperature, salinity and oxygen within the water column.

**A.22.** The diversity of phyla and life history strategies of ocean organisms create complex, interconnected food webs, often with many more levels than in terrestrial ecosystems.

**A.23.** Any change in an ecosystem or an organism in the community may have an adverse affect on many other ecosystems.

**B.2.** Many major groups (phyla and classes) of organisms, such as echinoderms, cephalopods, comb jellies and many types of worms are found exclusively in the ocean.

**B.4.** Most of the biomass in the ocean is made up of microscopic microbes.

**B.6.** Different ocean organisms have different life history strategies. Some drift with the currents (plankton), some swim (nekton), and some live on the bottom (benthos).

**B.7.** In the tropical ocean where there are fewer nutrients, diversity of life is higher and abundance of life is lower. In the polar regions where there are comparatively more nutrients, there is less diversity of life and more abundance of life.

**B.8.** Some ocean organisms, such as phytoplankton, have adaptations (e.g., oil droplets, spines and a large surface area), which allow them to stay near the sunlit surface where photosynthesis can occur.

**B.9.** Many marine animals, from shrimp to whales, rely on sound to communicate, find prey and mates, and sense their environments. Sound travels through the ocean much better than light does.

**B.10.** Some ocean organisms for living in or diving to the deep ocean. For example, elephant seals spend most of their life diving in the deep ocean to depths at which most mammals could not survive. Other organisms have bioluminescent lures to capture prey, or huge mouths and stomachs to take advantage of the scarce prey in the deep.

**B.11.** Organisms in the ocean exhibit an amazing variety of life cycles. Some have planktonic stages that help colonize new areas, some undergo long seasonal migrations to mate and have young, and others change sex as they mature or as the dominance hierarchy in the community changes.

**A.3.** Microbes (photosynthetic algae and bacteria) are important primary producers and support a huge abundance of life.

**A.6.** Ecosystems, such as deep sea vents and cold water seeps, depend on chemosynthesis—a process similar to photosynthesis, but with a different energy source—for primary productivity.

**A.9.** Coastal upwelling occurs when wind and the Coriolis effect push surface water offshore, allowing for cold, nutrient rich water from deeper down to rise to the surface.

**A.10.** Kelp forests and other coastal ocean ecosystems in upwelling zones have abundant sunlight, cold water and nutrients, making them some of the most productive ecosystems in the world.

**A.12.** A symbiotic relationship between corals and the algae living inside them allows the corals to thrive, even though the environmental conditions do not seem conducive to supporting life.

**A.17.** Ocean organisms are adapted to live in a relatively stable ocean. They are often adapted to tolerate very specific environmental conditions. For example, corals can only live within specific temperature ranges, and some larval fish can only live in very narrow layers of water with particular salinity and temperature.

**A.18.** Adaptations to specific environmental conditions can result in vertical and horizontal zonation patterns. For example, in intertidal areas, organisms are adapted to crashing waves and the cycle of the tides, while in the open ocean, many organisms are adapted to a specific temperature and salinity level. Different organisms are found in different density layers.

**A.19.** Humans have changed environmental conditions in the ocean, which has had a generally negative impact on organisms adapted to the previous conditions.

**A.20.** Changes to the climate will cause further changes to environmental conditions, which will likely have major impacts on many different ocean organisms.

**B.12.** Some of these life cycles are unique to ocean organisms, such as those of seahorses, corals, many fish and kelp.
